5. List

April 21, 2023

1 Introduction

- List is a collection which allows us to put many objects in a single object
- Lists are ordered and we have an index to access.
- Lists are created using square brackets.
- List items are ordered, changeable, and allow duplicate values.

2 Length of List

• Use len function

```
[8]: len(cities)
```

[8]: 4

```
[9]: len(even_nos)
```

[9]: 9

3 Empty List

```
[10]: el = list()
[11]: len(el)
[11]: 0
[12]: type(el)
[12]: list
[13]: el2 = []
```

4 Accessing elements of the List

- Elements of the List can be accessed using indexing
- We can use the index operator [] (square brackets) to access an item in a list.
- In Python, indices start at O(zero). So, a list having 5 elements will have an index from 0 to 4.
- Trying to access indexes other than these will raise an IndexError.
- The index must be an integer. We can't use float or other types, this will result in TypeError.
- Python allows negative indexing for its sequences. The index of -1 refers to the last item, -2 to the second last item and so on.

```
[14]: cities
[14]: ['bangalore', 'mumbai', 'delhi', 'kolkata']
[15]: cities[0]
[15]: 'bangalore'
[16]: cities[1]
[16]: 'mumbai'
[17]: cities[2]
[17]: 'delhi'
[18]: cities[3]
```

```
[18]: 'kolkata'
[19]: cities[-1]
[19]: 'kolkata'
[20]: cities[-2]
[20]: 'delhi'
[21]: cities[4]
                                                  Traceback (most recent call last)
       IndexError
       /tmp/ipykernel_7709/3265465078.py in <module>
       ----> 1 cities[4]
       IndexError: list index out of range
[22]: cities[-5]
                                                  Traceback (most recent call last)
       /tmp/ipykernel_7709/2986313696.py in <module>
       ----> 1 cities[-5]
       IndexError: list index out of range
     5 List Slicing
        • We can access a range of items in a list by using the slicing operator: (colon).
[23]: even_nos
[23]: [2, 40, 16, 8, 10, 62, 74, 98, 32]
[24]: len(even_nos)
[24]: 9
[25]: even_nos[2:8]
[25]: [16, 8, 10, 62, 74, 98]
[26]: even_nos[:6]
```

```
[26]: [2, 40, 16, 8, 10, 62]
[27]: even nos[3:]
[27]: [8, 10, 62, 74, 98, 32]
```

Modifying a List

- Lists are mutable, meaning their elements can be changed
- We can use the assignment operator = to change an item or a range of items.

```
[28]: cities
[28]: ['bangalore', 'mumbai', 'delhi', 'kolkata']
[29]: cities[2] = 'pune'
[30]: cities
[30]: ['bangalore', 'mumbai', 'pune', 'kolkata']
     6.1 Modify using index range
[31]: cities[1:3]
[31]: ['mumbai', 'pune']
[32]: cities[1:3] = ["chennai", "jaipur"]
[33]: cities
[33]: ['bangalore', 'chennai', 'jaipur', 'kolkata']
```

Properties of Lists

- 1. Heterogeneous (any data type!)
- 2. Ordered (numbered from 0 to n-1)
- 3. Have random access to any element (Using index)
- 4. Number of elements can change very easily.
- 5. Lists are mutable

Methods of List

- 1. append(elem)
- 2. extend(L)
- 3. insert(i, elem)

```
7. index(elem)
        8. count(elem)
        9. sort()
       10. reverse()
     8.1 append(elem)
        • Add item elem at the end of the list
[34]: cities
[34]: ['bangalore', 'chennai', 'jaipur', 'kolkata']
[35]: cities.append("pune")
[36]: cities
[36]: ['bangalore', 'chennai', 'jaipur', 'kolkata', 'pune']
     8.2 extend(L)
        • Add all items in given list L to the end
[37]: cities2 = ["mysore", "nagpur", "bhopal"]
[38]: cities.extend(cities2)
[39]:
      cities
[39]: ['bangalore',
       'chennai',
       'jaipur',
       'kolkata',
       'pune',
       'mysore',
       'nagpur',
       'bhopal']
     8.3 insert(i, elem)
        - Insert item elem at position \mathtt{i}
[40]: cities
```

4. remove(elem)
5. pop([i])
6. clear()

```
[40]: ['bangalore',
       'chennai',
       'jaipur',
       'kolkata',
       'pune',
       'mysore',
       'nagpur',
       'bhopal']
[41]: cities.insert(1, "mumbai")
[42]: cities.insert(-1, "Surat")
[43]: cities
[43]: ['bangalore',
       'mumbai',
       'chennai',
       'jaipur',
       'kolkata',
       'pune',
       'mysore',
       'nagpur',
       'Surat',
       'bhopal']
     8.4 remove(elem)
        • Remove first item that is equal to elem, from the list
[44]: cities
[44]: ['bangalore',
       'mumbai',
       'chennai',
       'jaipur',
       'kolkata',
       'pune',
       'mysore',
       'nagpur',
       'Surat',
       'bhopal']
[45]: cities.remove('mysore')
[46]: cities
```

```
[46]: ['bangalore',
       'mumbai',
       'chennai',
       'jaipur',
       'kolkata',
       'pune',
       'nagpur',
       'Surat',
       'bhopal']
     8.5 pop([i])
        • Remove and return item at position i (last item if i is not provided)
[47]: cities
[47]: ['bangalore',
       'mumbai',
       'chennai',
       'jaipur',
       'kolkata',
       'pune',
       'nagpur',
       'Surat',
       'bhopal']
[48]: cities.pop()
[48]: 'bhopal'
[49]: cities
[49]: ['bangalore',
       'mumbai',
       'chennai',
       'jaipur',
       'kolkata',
       'pune',
       'nagpur',
       'Surat']
[50]: cities.pop(3)
[50]: 'jaipur'
[51]: cities
```

```
[51]: ['bangalore', 'mumbai', 'chennai', 'kolkata', 'pune', 'nagpur', 'Surat']
[52]: c = cities.pop()
[53]: c
[53]: 'Surat'
     8.6 index(elem)
        • Return index of first item that is equal to elem
[54]: cities
[54]: ['bangalore', 'mumbai', 'chennai', 'kolkata', 'pune', 'nagpur']
[55]: cities.index('mumbai')
[55]: 1
[56]: cities.index('chennai')
[56]: 2
[57]: cities.append("mumbai")
     8.7 count(elem)
        • Return the number of items that is equal to elem
[58]: cities.count('mumbai')
[58]: 2
     8.8 sort()
        • Sort items in a list in ascending order
        • To sort in descending order use reverse = True
[59]: cities
[59]: ['bangalore', 'mumbai', 'chennai', 'kolkata', 'pune', 'nagpur', 'mumbai']
[60]: cities.sort()
[61]: cities
[61]: ['bangalore', 'chennai', 'kolkata', 'mumbai', 'mumbai', 'nagpur', 'pune']
```

```
[62]: cities.sort(reverse = True)
[63]: cities
[63]: ['pune', 'nagpur', 'mumbai', 'mumbai', 'kolkata', 'chennai', 'bangalore']
     8.9 reverse()
        • Reverse the order of items in a list
[64]: cities = ['bangalore',
       'mumbai',
       'Surat',
       'chennai',
       'jaipur',
       'kolkata',
       'pune',
       'nagpur',
       'Surat']
[65]: cities.reverse()
[66]:
     cities
[66]: ['Surat',
       'nagpur',
       'pune',
       'kolkata',
       'jaipur',
       'chennai',
       'Surat',
       'mumbai',
       'bangalore']
     8.10 clear()
        • Remove all items and empty the list
[67]: cities.clear()
[68]: cities
[68]: []
```

9 Deleting a List

• Use del

```
[69]: even_nos
[69]: [2, 40, 16, 8, 10, 62, 74, 98, 32]
[70]: del even_nos
[71]: even_nos
                                                 Traceback (most recent call last)
      /tmp/ipykernel_7709/1029312002.py in <module>
      ----> 1 even_nos
      NameError: name 'even_nos' is not defined
         Operators on List
     10
       1. Membership
       2. Arithmetic
     10.1 Membership
        • in
        • not in
[72]: multi
[72]: ['hi', 78, True, 3.14, 'sorry']
[73]: 78 in multi
[73]: True
[74]: 40 not in multi
[74]: True
[75]: 'hi' not in multi
[75]: False
[76]: True in multi
[76]: True
```

10.2 Arithmetic

• +

• *

```
[77]: p = [1, 2, 3]

q = [4, 5, 6]
```

11 Nested Lists

- List as a List element or we can say list inside a list
- Nested lists are accessed using nested indexing.

[81]: 'Monday'

[82]: [1, 2, 3]

[83]: 1

A matrix can be represented using a nested list

[86]: 3

12 split and join methods of String

12.1 split()

- The split() method splits a string into a list.
- You can specify the separator with sep, default separator is any whitespace.
- Maximum number of splits to do can be specified with maxsplit.

```
[87]: sentence = "When the winter comes, the lone wolf dies but the pack survives."
[88]:
      sentence.split()
[88]: ['When',
       'the',
       'winter',
       'comes,',
       'the',
       'lone',
       'wolf',
       'dies',
       'but',
       'the',
       'pack',
       'survives.']
[89]: sentence.split(",")
[89]: ['When the winter comes', ' the lone wolf dies but the pack survives.']
[90]: sentence.split(maxsplit=2) #maxsplit: Maximum number of splits to do.
[90]: ['When', 'the', 'winter comes, the lone wolf dies but the pack survives.']
     12.2 join()
        • The join() method takes all items in an iterable and joins them into one string.
        • A string must be specified as the separator.
        • Syntax: string.join(iterable)
[91]: sentence_list = ['When',
       'the',
       'winter',
       'comes,',
       'the',
       'lone',
       'wolf',
       'dies',
       'but',
```

```
'the',
       'pack',
       'survives.']
[92]: " ".join(sentence_list)
[92]: 'When the winter comes, the lone wolf dies but the pack survives.'
      seperator = " "
[93]:
[94]: seperator.join(sentence_list)
[94]: 'When the winter comes, the lone wolf dies but the pack survives.'
          For Loop on List
     13
[95]: sentence_list
[95]: ['When',
       'the',
       'winter',
       'comes,',
       'the',
       'lone',
       'wolf',
       'dies',
       'but',
       'the',
       'pack',
       'survives.']
[96]: for i in sentence_list:
          print(i)
          print('.-'*4)
     When
     .-.-.-
     the
     .-.-.-
     winter
     .-.-.-
     comes,
     .-.-.-
     the
     .-.-.-
     lone
```

```
.-.-.-
wolf
.-.-.-
dies
.-.-.-
but
.-.-.-
the
.-.-.-
pack
.-.-.-
survives.
```

13.1 Nested For Loop
